

Andrews Lake

17.5 acres
Frederica

Largemouth bass were moderately abundant with high numbers of sub-adult (8 to 12 inch) group. Weights were satisfactory.

Lower numbers of bluegill were evident with the dominant size group less than six inches. However, a few bluegill were good size (> 8 inches). Black crappie numbers have increased over historical levels but remain low. They exhibit a wide size range with citation-size fish (> one pound) available.

American eel were very abundant, while golden shiners, chain pickerel, and brown bullhead were less common. Neither yellow nor white perch were collected in 2012 although they had been present in low numbers historically.

VEGETATION

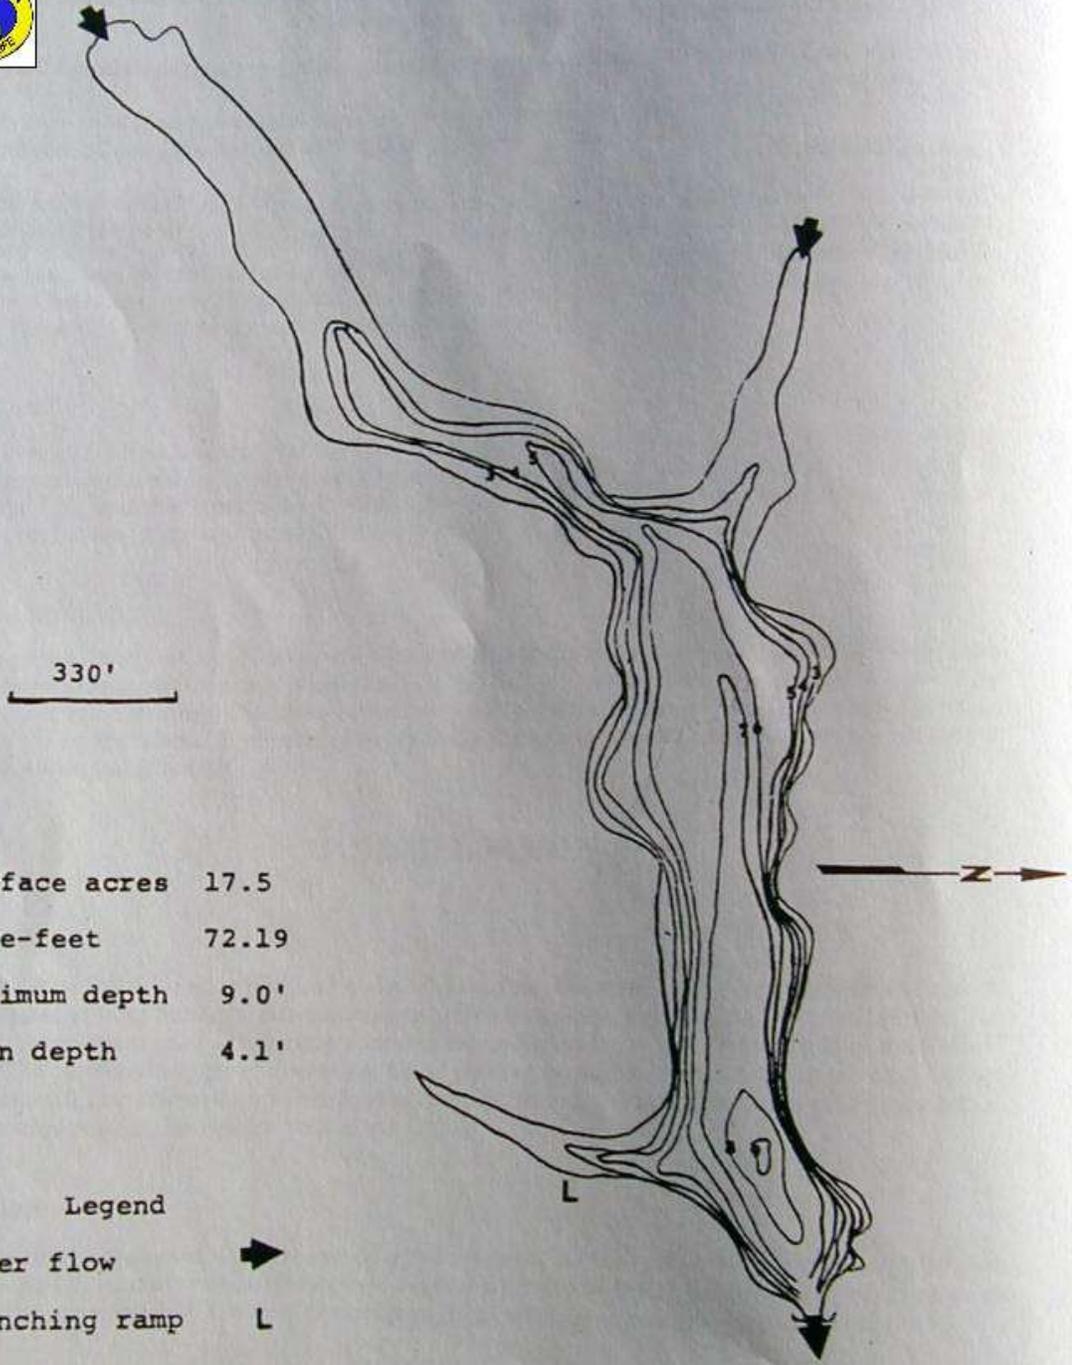

This small lake has a long history of periodic algae problems but herbicide applications have generally been successful on a short-term basis. Occasionally small patches of the non-native aquatic plant, parrot-feather, have been noted but have been treated by herbicides as well. However, spring 2012 this plant was observed distributed throughout much of the pond along the shoreline edges. Floating mats of filamentous algae often collect along the shoreline, in the back of coves, and in front of the water control structure.

Extensive beds of spatterdock are the dominant emergent plant feature of this pond, especially in the upstream portion. Small amounts of duckweed often blow around the surface with the prevailing winds.

SPECIAL CONDITIONS

Since much of the shoreline is residential, bank fishing is limited to the access area and the shoreline between the boat ramp and the water control structure. The protected slot size limit for bass was removed from this pond effective April 2010. The statewide bag limit of 6 bass per day and minimum size limit of 12 inches in now in effect here.
